

If Greece Has Recovered, Why Do So Many Households Still Struggle?

Greece's labour market recovered faster than its households. The distance between income poverty and reported hardship shows what the recovery headlines leave out: a moving poverty line, damaged wages, pressure on purchasing power and the long shadow of the crisis.

5. The Accumulated Weight of the Crisis

Whether the length of the crisis still matters today.

6. What Remains Open

Two questions where the available data give a more limited answer.

7. What the Numbers Still Miss

Factors that were tested, and factors that were not.

8. What It Adds Up To

How the story ends.

The Poverty Rate Says One Thing. Households Say Another.

There is a strange reversal in the public debate about Greece's economy. When unemployment falls or GDP grows, the indicators are treated as the final proof of recovery. But when two in three households say they struggle to make ends meet, attention shifts away from the indicators and towards household behaviour: coffee, takeaway food, travel, “exaggeration”, or Greek pessimism.

Is that shift justified? By the official income-poverty measure, Greece is in difficulty but not outside the European range. By what households report, it is almost in a category of its own. That is the paradox this piece unfolds: *income poverty* and *reported hardship* are telling two different stories. The question is whether the second is merely a darker way of answering, or whether it captures a material reality that the first measure cannot see on its own.

Two measures carry this whole piece. Income poverty, officially at-risk-of-poverty or *AROP*, is an income test: a person counts as poor if the income shared across their household, adjusted for household size, sits below 60% of the country's median, recalculated every year. Reported hardship is different and more direct: in an EU-wide survey, households are asked whether they can make ends meet, and those who say they manage only “with difficulty” or “with great difficulty” count as struggling.

FIGURE 1 Greece Is Far Above the Poverty-Hardship Line

Does official income poverty account for the hardship Greek households report?

▼ Methods and limits

Read with this. Descriptive comparison of two official measures. Reported hardship is answered by HOUSEHOLDS and income poverty counts PEOPLE, so the axis is labelled percent rather than either. In the second view the fitted line excludes Greece, describing the European pattern Greece is being judged against rather than one Greece helped set. The labelled point marks the median country on each measure taken SEPARATELY, so it is a reference point rather than an actual country: no member state necessarily sits there. Both views are country-level and say nothing about any individual household.

How Greece's hardship gap developed										
Series	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Greece: reported hardship	77.7	76.8	77.2	74.1	71.0	69.8	71.0	68.4	67.0	66.7
EU median: reported hardship	28.9	25.9	22.6	20.5	18.5	16.8	15.4	17.9	16.6	17.1
Greece: income poverty	21.4	21.2	20.2	18.5	17.9	17.7	19.6	18.8	18.9	19.6
EU median: income poverty	16.3	16.5	15.9	16.4	15.4	16.1	15.7	15.6	15.4	15.5

Estonia	20.2	9.9
Croatia	20.3	19.8
Lithuania	21.5	11.4
Latvia	21.6	23.3
Bulgaria	21.7	37.4

[Figure 1's first tab](#), “How Greece's hardship gap developed”, puts those two measures side by side and shows why the paradox holds. Since 2015, Greece's reported hardship has never dropped below

two-thirds of households: it opens near 78% and eases only gradually. Its income-poverty rate spends the same decade hovering near a fifth, barely moving at all. Both EU medians sit far beneath Greece's line for reported hardship, the whole way through. (The EU median is the middle EU country on that measure, not an EU-wide average.) This isn't a single bad year showing up once. It's been the shape of an entire decade.

Switch to the [second tab](#), “Where countries stood in 2024”, and the gap turns from a Greek pattern into a European outlier. Each grey dot is an EU country. The horizontal axis is income poverty; the vertical is reported hardship. The dotted line is the relationship the other twenty-six countries actually follow. Greece is the blue point far above it. At Greece's income-poverty rate, that relationship predicts about 20% of households struggling to make ends meet. Greece reports about 67%. The 47-percentage-point distance between those two numbers is the gap this piece tries to understand.

Greek subjective hardship runs 52.6 points above relative income poverty on average, and Greece ranks first of 27 on hardship while ranking seventh on AROP.

▼ Why the chart starts in 2015

Not because Eurostat's data is that young: it's where Greece's own hardship gap is clearest. The indicator can be reconstructed back past 2010 too, and this project checked that reconstruction against the official series everywhere the two overlap, but nothing later in this piece relies on it.

The outcome is Eurostat's official subjective-hardship indicator, extended backwards before 2010 using a constructed series validated against it on 432 overlapping country-years.

The limits of this. pre-2010 provenance is ours, not Eurostat's.

The two numbers are not rival opinions. They come from the same European system, from surveys of the same households, but they ask different kinds of questions: one about income relative to everyone else, one about a household's own sense of its budget. In most of Europe, those two answers move together. In Greece, they have stayed far apart, year after year.

But once a gap like that appears, the two numbers are not usually read with equal trust. Income poverty feels firmer: a number built from income, thresholds and ranks. Reported hardship feels softer: not necessarily a fact about a household's circumstances, but the way that household describes itself. Is that fair? Or is the hardship signal telling us something material that income poverty alone cannot see?

This Was Not Just a Feeling

If Greek households are simply answering a subjective question more darkly than everyone else, then this is a story about how people talk about their lives, not about poverty. Everything the rest of this piece does next would be measuring an echo, not an economy. That has to be settled first, and settled seriously, not waved off as an obvious no.

The test isn't whether one household's answer feels convincing on its own. It's whether the national annual rate of that feeling moves together, year after year, with the national annual rates of things that name actual events, not moods: *falling behind on bills*, *being unable to cover a surprise expense*, *being unable to heat the home properly*, and *material deprivation*, going without several ordinary things at once. A vague question can drift with a bad national mood. A national mood drifting in step with four separate, concrete annual rates, year after year, is a much harder thing for mood alone to produce.

FIGURE 2 Hardship Moves With Concrete Financial Strain

Did concrete affordability difficulties rise and fall with what Greek households reported?

▼ **Methods and limits**

Read with this. Same-survey corroboration, not independent validation or causal evidence. Greek correlations with reported hardship: unexpected expenses 0.92 · material deprivation 0.94 · keeping the home warm 0.87 · falling behind on bills 0.37. Every line is a distance from its own 2015–2024 average, including the European median, so three series on different scales can share one axis: the shapes may be compared, the levels may not. The scale is the same in all four tabs. European median hardship is deliberately absent, since the question here is whether the concrete difficulty moved with Greek reports, not how Greece compares.

Unexpected expenses										
Year	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Greece: reported hardship	5.7	4.8	5.2	2.1	-1.0	-2.2	-1.0	-3.6	-5.0	-5.3
Greece: unexpected expenses	4.7	4.9	4.0	1.7	-0.9	2.0	-2.4	-5.1	-4.4	-4.8
EU median: unexpected expenses	7.5	5.6	2.5	-0.2	-0.9	-1.8	-4.7	-1.1	-2.9	-3.6

Material deprivation										
Year	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Greece: reported hardship	5.7	4.8	5.2	2.1	-1.0	-2.2	-1.0	-3.6	-5.0	-5.3
Greece: material deprivation	2.0	2.8	2.7	0.5	0.2	-0.7	-1.7	-1.7	-2.1	-1.6
EU median: material deprivation	2.3	1.2	0.8	-0.1	-0.5	-1.0	-0.7	-0.6	-0.6	-1.2

Keeping the home warm										
Year	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Greece: reported hardship	5.7	4.8	5.2	2.1	-1.0	-2.2	-1.0	-3.6	-5.0	-5.3
Greece: keeping the home warm	7.6	7.5	4.1	1.1	-3.7	-4.5	-4.1	-2.9	-2.4	-2.6
EU median: keeping the home warm	1.5	-0.1	-0.2	-0.9	-0.6	-0.3	-1.1	0.8	1.1	-0.0
Falling behind on bills										
Year	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Greece: reported hardship	5.7	4.8	5.2	2.1	-1.0	-2.2	-1.0	-3.6	-5.0	-5.3
Greece: falling behind on bills	5.8	4.4	1.4	-0.5	-2.1	-6.6	-7.1	2.0	3.8	-0.7
EU median: falling behind on bills	1.9	2.2	0.3	0.9	-0.1	-1.3	-1.2	-1.5	-0.5	-0.9

[Figure 2](#): three of the four tabs tell the same story, each as a correlation, where close to 1 means two measures rise and fall together and close to 0 means no strong straight-line relationship shows up between them. In Greece's own year-by-year data, *reported hardship* tracks an inability to cover a surprise expense almost exactly ([Unexpected expenses](#)) at 0.92. It tracks going without several ordinary things at once even more closely ([Material deprivation](#)), at 0.94. It tracks struggling to keep the home warm at 0.87 ([Keeping the home warm](#)). When one line moves, the others move with it, year after year. And this isn't a Greek peculiarity. Pooled across all twenty-seven EU countries, comparing each country with itself over time rather than just rich countries with poor ones, the same relationships hold, at 0.63 to 0.80.

Reported difficulty co-moves with arrears, inability to meet an unexpected expense, inadequate heating and severe deprivation at within-country correlations of 0.63 to 0.80.

The limits of this. same-instrument corroboration, NOT independent validation; all items and the outcome come from EU-SILC; not uniform: arrears within Greece is 0.371.

The fourth tab ([Falling behind on bills](#)) tells a different story, and it's worth sitting with why. Falling behind on bills, the one item that sounds like the hardest, most factual anchor of the four, tracks reported hardship at only 0.37, by far the weakest of the set. Falling behind requires having had credit and obligations to fall behind on in the first place. A household that lost access to credit years ago, or never had any to lose, can be in real difficulty without that difficulty ever showing up as an unpaid bill. The weakest link in the evidence has a plausible, ordinary explanation, not a suspicious one — though this project did not test that explanation directly.

None of this is independent proof, and that has to be said plainly rather than buried. Every one of these items comes from the same survey as the question about making ends meet, and may share a

common way of answering it. A household in a genuinely grim mood could rate the whole set grimly, and that alone would produce numbers like these. What's been shown is that reported hardship is coherent with concrete circumstances. It hasn't been shown, and can't be shown this way, that it's confirmed by something entirely outside the survey.

There is a second, different kind of check, and it does not depend on the same hardship questions. If this one number were an isolated fluke, one instrument twitching on its own, it should stand apart from everything else describing Greek life. It doesn't.

FIGURE 3 The Problem Spread Across the Dashboard

Did Greek disadvantage deepen on a few measures, or spread across many?

▼ Methods and limits

Read with this. Descriptive summary of the condition, not a predictor of it. DESCRIPTIVE ONLY. Breadth was tested as an incremental predictor of reported hardship in the reference model and does not survive: on its own it is not significant ($p = 0.12$), and once the other accumulated measures enter the model its coefficient reverses sign. It summarises the condition rather than explaining it. THE BASKET IS FIXED: these are the 16 indicators with a valid EU position in both 2008 and 2024, chosen without reference to whether they improved or deteriorated, so the same things are counted at both ends and in every year between. Unemployment, youth unemployment and the employment rate are absent because comparable EU coverage for them begins in 2009; hours worked, pay per hour, the work-effort squeeze and real wages are all present, so this is not a basket without labour-market information. The outcome and every model covariate are excluded. THE EU-COUNTRY MEDIAN is the median of the 27 member states' own shares on this basket -- a median across countries, not Eurostat's population-weighted EU aggregate -- named accordingly rather than simply 'EU'. Croatia never reaches full 16-indicator coverage in any basket year and does not appear as a line for that reason. The 'Which measures' view's axis is POSITION, not value: the indicators have no common unit, so 0 is the best place in the Union to be on that indicator and 100 the worst, whichever direction 'worse' runs in.

Of 16 indicators, **4 were already in the EU's worst fifth in 2008, 7 entered it by 2024, and none left.**

		Which measures																
Series	2008 position					2024 position							Transition					
Hours worked against hourly pay	59.3					100.0							entered worst fifth					
Prices measured against wages	48.1					100.0							entered worst fifth					
Pay per hour worked	55.6					100.0							entered worst fifth					
Household income after inflation	51.9					100.0							entered worst fifth					
Wages after inflation	51.9					100.0							entered worst fifth					
The poverty line after inflation	51.9					100.0							entered worst fifth					
Keeping the home warm	73.1					98.1							entered worst fifth					
Hours worked each week	94.4					100.0							already worst fifth					
What households expect of the year ahead	100.0					100.0							already worst fifth					
Citizens leaving the country	86.4					96.2							already worst fifth					
Income inequality	80.8					81.5							already worst fifth					
Food prices	14.8					77.8							outside both years

Prices overall	53.7					70.4							outside both years					
Housing and energy prices	63.0					59.3							outside both years					
What households actually spend	48.1					48.1							outside both years					
How many measures																		
Series	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	
Greece	25.0	18.8	43.8	50.0	50.0	50.0	43.8	50.0	50.0	62.5	56.2	56.2	56.2	56.2	56.2	62.5	68.8	
EU-country median	6.2	12.5	9.4	12.5	18.8	18.8	15.6	12.5	18.8	18.8	12.5	12.5	18.8	12.5	12.5	18.8	12.5	

Take *sixteen separate measures* of Greek life (see [Figure 3](#)): wages, hours worked, prices, keeping the home warm, what households expect of the coming year, income inequality. They were filtered from a wider set of economic and social indicators to only those with a valid reading in both 2008 and 2024, so the count couldn't grow just because more things got measured later, and selected without regard to whether each one improved or worsened, so there was no room to cherry-pick which sixteen made the basket. The first tab ([Which measures](#)) lays out where Greece sat on each one, in 2008 and again in 2024, and whether it crossed into the EU's worst fifth, the bottom 20% of member states on that measure, or was already there. The point isn't that every one of them moved identically. It's that disadvantage spread across the dashboard, not just in one place.

Switch to the second tab ([How many measures](#)) and that spread turns into a single line. Before the crisis, Greece sat in the worst fifth of the EU on four of the sixteen, a quarter. Now it sits there on eleven, two thirds of the whole set. Plotted alongside it, the EU-country median barely moves over the same seventeen years. This isn't a general European drift. Most of these measures don't come from the same interview as the hardship question, either.

The list is not hand-picked. It includes every indicator in the project with a valid EU position in both 2008 and 2024, selected before looking at whether Greece improved or worsened. That is why some obvious labour-market measures are absent here: their comparable EU series begin in 2009, one year too late for the fixed 2008 basket. [The appendix shows](#) the fixed basket and the wider candidate set.

One more thing is worth mentioning here, carefully. Put the closest hardship items into the same statistical picture as the official poverty rate, and much of Greece's excess stops standing apart. That matters. But it also carries the same-survey problem all over again, in a sharper form. And it returns later in this piece, because it turns out to be exactly the point where the explanation looks strongest and least independent.

Those same four items statistically absorb 71% of Greece's baseline residual (+46.92 to +13.74).

The limits of this. ABSORPTION, never explanation; shared instrument is not shared cause; diagnostic only; never a headline explanation.

So the hardship signal is too materially connected to dismiss as mood. It is also too close to the same survey instrument to call independently proven. Both of those are true at once, and the honest version of this section holds them together rather than picking one. What it does settle is enough to move forward on: if the difficulty is real, why doesn't the official poverty rate register it?

The Ruler Moved With the Fall

One answer starts with the ruler itself: the official poverty line isn't fixed. It moves with the very economy it is supposed to be measuring.

The EU's headline poverty measure, at-risk-of-poverty, rests on a line that isn't fixed in money terms. That line is set at 60% of whatever the national median income happens to be, *that year*, and *AROP* itself is the share of people whose income falls below it. In an ordinary economy, where incomes drift up slowly and roughly together, that is a reasonable way to define being poor relative to your neighbours.

Greece's economy, from 2010, was not ordinary. Incomes fell together, hard and fast, and when the median falls, the poverty line falls with it. A household earning exactly what it earned five years earlier could find itself reclassified from poor to not poor, not because anything in its life had improved, but because the ruler measuring it had shrunk to match the collapse around it.

FIGURE 4 The Poverty Line Looked Stable. Its Value Did Not.

What happened to the line Greek poverty is measured against, and what does a fixed line show instead?

▼ **Methods and limits**

Read with this. The anchored series is an approximation built in this project and is labelled as such wherever it appears. The first view counts PEOPLE, the second counts EUROS. In the second, both lines are the same official threshold: one as published in each year's own money, the other converted into what it could buy in 2008. The cash line recovers and the purchasing-power line does not, and that difference is why the first view's two counts diverge. Both views are Greece only and support no cross-country statement.

Who falls below a fixed line																							
Series	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	
Greece: fixed 2008 threshold	25.6	22.8	20.7	21.5	21.2	19.7	17.0	18.0	24.6	33.3	39.7	40.6	39.8	39.8	38.3	37.3	34.6	30.8	32.7	33.6	32.0	30.3	
Greece: current-year threshold	20.7	19.9	19.6	20.5	20.3	20.1	19.7	20.1	21.4	23.1	23.1	22.1	21.4	21.2	20.2	18.5	17.9	17.7	19.6	18.8	18.9	19.6	
What the line itself is worth																							
Series	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Threshold in cash terms	4923	5306	5650	5910	6120	6480	6897	7178	6591	5708	5023	4608	4512	4500	4560	4718	4917	5269	5251	5712	6030	6510	7020
Same threshold in 2008 purchasing power	5819	6089	6264	6343	6377	6480	6808	6768	6027	5168	4589	4270	4228	4216	4226	4338	4498	4884	4838	4815	4878	5113	5358

Figure 4's first tab ([Who falls below a fixed line](#)) makes the moving-ruler problem visible: the official poverty rate barely moves because the line is allowed to fall with the national median. Hold the 2008 line fixed in real terms instead, and measured poverty roughly doubles, peaking above 40% in 2014. The second tab ([What the line itself is worth](#)) shows the mechanism more plainly still: the threshold may look stable in cash terms, but what it can actually buy collapsed, and has only partly recovered.

DESCRIPTIVE CORROBORATION

ANCHORED POVERTY, CORROBORATED BY INDEPENDENT MICRODATA

Independent microdata points the same way. A separate study, using Greek household microdata, estimates that 48% of the population was poor under a poverty line anchored before the crisis, for the same income year this project's own reconstruction puts at 40.6%.

What this lets us say. Independent microdata evidence points in the same direction: a fixed pre-crisis poverty line shows much larger crisis-era poverty than contemporaneous AROP.

What it does not. Treating 48% against 40.6% as a direct validation test, a bias estimate, or proof that this project's reconstruction is too low by seven to eight points -- the two differ in data, anchor year, price adjustment and vintage.

Andriopoulou, E., Kanavitsa, E. & Tsakloglou, P. (2020), Decomposing Poverty in Hard Times: Greece 2007-2016. LSE GreeSE Paper No. 149. [source](#)

That doesn't make the *fixed poverty line* the “correct” one, and this project's own reconstruction of it says nothing about how Greece compares to any other country: it measures Greece against its own past, not against Europe. It asks a different question: the official rate measures who is far below the middle of *today's* Greece; the fixed line asks how many people are below a pre-crisis standard. When a whole country falls together, those two questions split apart.

Europe's broader measure, *AROPE* (at risk of poverty or social exclusion), tries to widen the lens. It counts anyone who meets at least one of three conditions — income poverty, severe material deprivation, or *very low work intensity* — rather than income poverty alone, so it should close the gap if the problem is only that income poverty is too narrow. It does close some of it: 9.8 of the 52.6 points, under a fifth. But it leaves most of the distance untouched, and its contribution shrinks over the decade.

Switching to AROPE closes 9.8 of those 52.6 points (19%), leaving 42.8 unexplained, and its contribution shrinks from 11.0 points in 2015 to 7.3 in 2024.

FIGURE 5 Where AROPE Sits, What It's Made Of, and Who Carries It

Where does AROPE sit against income poverty and reported hardship, what is AROPE made of, and did every age and sex group move the same way?

▼ Methods and limits

Read with this. These are changes in group-level rates, not evidence about the same individuals over time. The 2024-2025 national increase was driven primarily by within-group changes, especially deterioration among people aged 65+, rather than population ageing. AROPE components are a UNION and may not be summed. Very low work intensity is part of AROPE, but the project does not hold a comparable national-total series for the Components view; its available age coverage uses a different population base, and aggregate component rates cannot reconstruct the AROPE union in any case. In all four views colour marks the measure or group and dash marks the country, so each Greek line is paired with the EU median for the same thing in the same colour. The per-component views with every other member state drawn behind are in the statistical appendix.

Figure 5 shows both sides of that result. The first tab ([Headline measures](#)) places income poverty, *AROPE* and reported hardship together: *AROPE* sits between them, but much closer to income poverty than to hardship. The other tabs show why one national number is still too smooth. Greece sits above the EU median on the two components with a comparable national series, income poverty and material deprivation; the third, very low work intensity, has no comparable national series and

isn't shown. Older people move in the opposite direction from everyone younger; women remain above men throughout. The point isn't any one split on its own. It's that the national average compresses very different household positions into one line.

The official measures are not wrong. They are doing exactly what they were built to do. But they measure position, broadened risk and national averages. The household answering the hardship question is answering something narrower and more immediate: what daily life costs against its own budget. That is where the next part of the story has to go.

The Jobs Came Back. The Household Economy Did Not.

The strongest case for Greece's recovery is the labour market. Unemployment fell from its crisis peak to under 9%, and *long-term unemployment* fell with it. That is real recovery. But a household does not live on the unemployment rate. It lives on the wage that arrives, the prices facing that wage, what it costs to keep a roof over its head, and what is left when the month runs out. On that test, Greece's recovery looks much less complete.

Start with the part that clearly improved: long-term unemployment, meaning worklessness lasting twelve months or more. It stood at 16.4% of the labour force in 2015. By 2024 it had fallen to 5.4%. That is substantial progress. It means fewer households spent years outside work — the kind of prolonged spell that often forces a household to run through savings, sell what it can, or lean on relatives, even though this project did not track those responses directly.

But employment recovered furthest, and it was not the whole household story. Greek *real wages* stood at about 77% of their 2008 level in 2015; by 2024, about 68%. Not recovering slowly. Not recovering. Greek wages have now been below their pre-crisis level for fifteen consecutive years, longer than any EU country except Hungary. Output per person sits between the two stories: the shortfall against Greece's own 2008 peak roughly halved, but it did not close. *Actual individual consumption* — the volume of goods and services households actually consume, measured in a common purchasing-power unit that strips out price-level differences between countries, not literal euros — did rise substantially, from roughly 14,800 to 21,300 in that unit. That is real, and worth saying plainly, because a piece about hardship can leave the impression that nothing improved. But the EU median rose faster over the same years, so the distance between Greece and other EU countries widened even as Greece's own number climbed.

FIGURE 6 Some Gaps Closed. Others Widened.

Which measures converged toward the EU and which diverged?

▼ Methods and limits

Read with this. A NARROWING GAP DOES NOT MEAN GREECE IMPROVED. A gap can close because Greece caught up, because the rest of the EU deteriorated, or because everyone moved in the same direction at different speeds. This chart measures RELATIVE CONVERGENCE, not national recovery, which is why both endpoints for Greece and for the EU median are in the tooltip and the table. "71% of the gap closed" and "conditions improved by 71%" are entirely different claims. The plotted quantity is dimensionless because the underlying gaps are measured in percentage points, index points and PPS per head and cannot share an axis.

Measure	Share of 2015 gap closed	Greece 2015	Greece 2024	EU median 2015	EU median 2024	Gap 2015	Gap 2024
Long-term unemployment	0.71	16.40	5.40	3.60	1.70	12.80	3.70
Share below own GDP peak	0.55	24.84	11.20	0.00	0.00	24.84	11.20
Housing-cost overburden	0.40	45.50	28.90	8.70	6.70	36.80	22.20
AROPE	0.26	32.40	26.90	22.50	19.60	9.90	7.30
Income poverty (AROP)	0.20	21.40	19.60	16.30	15.50	5.10	4.10
Real poverty threshold	0.02	65.14	78.77	106.45	119.11	-41.31	-40.34
Material deprivation	0.01	17.60	14.00	7.80	4.30	9.80	9.70
Reported hardship	-0.02	77.70	66.70	28.90	17.10	48.80	49.60
Real household income	-0.06	67.79	84.13	102.25	120.59	-34.46	-36.46
Hardship gap against income poverty	-0.06	56.30	47.10	13.10	1.20	43.20	45.90
Hardship gap against AROPE	-0.08	45.30	39.80	6.40	-2.30	38.90	42.10
Real wages	-0.78	76.91	68.18	101.43	111.85	-24.52	-43.67
Material resources	-0.93	14769.70	21309.90	16230.40	24129.10	-1460.70	-2819.20
Wage-adjusted affordability	-2.55	141.89	173.09	127.22	120.97	14.67	52.12

[Figure 6](#) shows the shape: gaps that were mostly about jobs and housing narrowed considerably; the output gap narrowed too, but only by about half; gaps that were about wages, resources and what money can buy narrowed barely at all, or widened. But a chart built to fit fourteen measures onto one axis has to abstract away units, so [the table below](#) gives the same story in the numbers each measure actually reports in, and the plainest reading of each.

MEASURE	GREECE, 2015→2024	EU MEDIAN, 2015→2024	WHAT ACTUALLY HAPPENED
Long-term unemployment	16.4% → 5.4%	3.6% → 1.7%	Large improvement; Greece remained above the
Share below own GDP peak	24.8% → 11.2%	0.0% → 0.0%	Substantial but incomplete recovery
Housing-cost overburden	45.5% → 28.9%	8.7% → 6.7%	Improved, but the remaining disadvantage was
Real wages, 2008 = 100	76.9 → 68.2	101.4 → 111.8	Greece fell further behind
Material resources	14,770 → 21,310 PPS	16,230 → 24,129 PPS	Resources rose in Greece, but more slowly than
Wage-adjusted affordability	141.9 → 173.1	127.2 → 121.0	Affordability pressure deteriorated sharply relat

The table gives the same comparison in each measure's own units: percentages for unemployment, output and housing costs; a common purchasing-power unit for material resources; index points for wages and affordability. It also keeps the main caution visible: an improving Greek number is not always a closing gap. Material resources rose sharply in Greece but fell further behind, because the EU median rose faster. And a narrowing gap does not tell us why it narrowed. It only shows the shape of recovery: employment improved most clearly, while wages, resources and purchasing power remained much more damaged.

FIGURE 7 Recovery Looks Weaker From the Household Budget

What do the three supported constructs actually look like for Greece against the EU?

Long-term unemployment										
Series	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Greece	16.4	15.4	14.3	12.5	11.3	10.5	9.2	7.7	6.2	5.4
EU median	3.6	3.1	2.7	2.1	1.9	1.8	2.0	1.9	1.7	1.7

Material resources										
Series	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Greece	14770	14786	15372	15833	16372	15475	16772	19402	20701	21310
EU median	16230	16494	17038	18006	18707	17386	19479	21317	23055	24129

Wage-adjusted affordability										
Series	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Greece	141.9	148.6	148.2	156.8	162.2	163.3	165.6	171.2	173.1	173.1
EU median	127.2	124.7	124.6	119.8	118.4	117.7	120.2	120.7	122.3	121.0

That same split appears when we stop looking at gaps and look at today's levels, in [Figure 7](#). Long-term unemployment, material resources and *wage-adjusted affordability* each place Greece on the wrong side of the European middle. They are also the three current conditions that carry information beyond the official poverty rate. But the point here is simpler: household recovery looks weaker than headline recovery.

A country can score badly on affordability two ways: by being expensive, or by paying poorly. Greece does both at once, and a household experiencing it does not much care which half is responsible.

Precise result. Long-term unemployment, material resources and wage-adjusted affordability each predict reported hardship beyond income poverty and year effects.

Limits. Cross-country association, not causal evidence; wage-adjusted affordability should not be read together with the work-effort-squeeze measure.

DESCRIPTIVE CORROBORATION

INDEPENDENT DESCRIPTIVE CORROBORATION (GREECE IN FIGURES)

A newer Greece in Figures analysis reaches a similar descriptive picture from outside this project's models: Greece is not last in Europe on actual consumption, but it combines long working hours, low hourly reward and high everyday prices. That does not test this report's explanation, and it uses a newer data vintage, but it independently points to the same household-budget pressure.

▼ The full caveat

What this lets us say. The independent picture -- Greece not last on actual consumption, long hours for comparatively low hourly reward, high relative prices in food and information/communication -- is consistent with and external corroboration for this project's own material-resources and wage-adjusted-affordability findings. Its central descriptive numbers reproduce against the primary Eurostat and ELSTAT releases they draw on.

What it does not. Treating the article's own comparisons, or its constructed AIC-per-hour ratio, as inferential evidence: it applies no bootstrap, no FDR correction, no within/between decomposition and no model comparison, and it does not test whether these factors account for reported hardship. Merging its 2025/2026-vintage figures into this project's frozen 2015-2024 panel. Repeating its car-ownership sentence, which cites a vehicle-STOCK figure as evidence of new purchases, or its 'all Greeks travelled' generalisation, which the underlying ELSTAT survey does not support. Reading its AIC rank, hours rank or price-level figure as contradicting this project's own numbers without first noting the different vintage or aggregate behind each.

Greece in Figures, "Γιατί οι Έλληνες νιώθουν τόσο φτωχοί" [Why Greeks feel so poor]. [source](#)

Put simply: the labour market improved, but the household budget did not recover with it.

“The unemployment rate came back. The paycheck did not.”

The Accumulated Weight of the Crisis

The jobs came back. The household economy did not. But even that distinction still looks mostly at where things stand now. For households, duration matters: one year of unemployment is not the

same as ten. A wage cut that lasts one year is not the same as one that lasts fifteen. Housing pressure that spikes and disappears is not the same as pressure that accumulates.

This is also the point where the story is easiest to overstate.

Instead of asking only how bad a condition is today, this section asks how much of it a country has carried since the crisis began: *accumulated excess unemployment*, how much a country has accumulated since the crisis began; *wage duration below 2008*, how many consecutive years its wages stayed below that level; and *housing-cost deterioration*, how much its housing costs have deteriorated since 2010.

FIGURE 8 Greece Had Among Europe's Largest Accumulated Burdens

How much accumulated unemployment, wage non-recovery and housing-cost deterioration has each country absorbed, and where does Greece sit?

▼ Methods and limits

Read with this. cross-country association | no demonstrated within-Greece dynamic | no causal claim | current conditions not ruled out The three measures are in different units and may not be compared with each other: accumulated unemployment and housing deterioration are percentage-point-years, wage non-recovery is a count of consecutive years.

[Figure 8](#) is the balance sheet the crisis left behind. Greece carries the heaviest accumulated unemployment burden in the EU, and the worst housing-cost deterioration since 2010; both rank first of 27. On wage duration it's not the heaviest: Hungary has gone slightly longer, sixteen consecutive years below its 2008 level to Greece's fifteen. The chart shows every country, not just Greece, so that one exception is visible rather than buried.

Carrying a heavy history is one thing. Whether that history still matters once you already know where a country stands today is a harder question, and a more important one: if you know this year's unemployment rate, does the decade behind it tell you anything more?

For three measures, it does. Countries carrying more accumulated unemployment, more years of wages below 2008, and more housing-cost deterioration report more hardship, even after today's poverty rate and current conditions are already accounted for.

Precise result. Accumulated excess unemployment, wage duration below 2008, and housing-cost deterioration each still predict reported hardship once today's poverty rate and current conditions are controlled for.

Limits. Cross-country association, not causal evidence, and not a demonstrated change within Greece over time.

The wage-duration result holds for one specific way of counting consecutive years below 2008; other reasonable ways of counting the same idea point the same direction without quite clearing the bar. The housing result is the shakiest of the three, and it's presented that way rather than rounded up to a clean yes.

The pattern is not universal, though, which is itself informative. For *wage-adjusted affordability*, it runs the other way: today's number carries the signal, and the accumulated version of it doesn't resolve.

Precise result. For wage-adjusted affordability the pattern reverses: the current measure survives conditioning while the accumulated one remains inconclusive.

Limits. Inconclusive, not unsupported.

Compounded inflation was also tested as an accumulated measure, but the result remained inconclusive under the available statistical power.

The contrast argues against treating accumulated history as a universal rule. It suggests these results are specific to work, wages and housing rather than some broad law that the past always counts for everything.

One more piece of the history simply isn't there to look at. What households could actually afford, tracked back to before the crisis, can't be built at all: the source data only starts in 2015, already years into the recovery. Moving the starting line later, to when the data actually begins, would have solved the data problem and created a different one: a measure that could no longer see the crisis it exists to describe. So it stays out, and is named here rather than quietly absent.

Accumulated material resources could not be tested at all: the source series begins in 2015 and no 2008 baseline exists. The baseline was not moved to make it testable.

The limits of this. infeasible, not null.

The accumulated wage-shortfall coefficient cleared every conditional gate but its prior stage did not support it, so the pre-registered ceiling caps it. It is reported and is not a finding.

The limits of this. capped by the no-promotion rule: it may only qualify or withdraw support.

A related wage measure creates the opposite problem. On the face of the numbers, *accumulated wage shortfall* looks convincing. But it cannot be counted here, because the earlier stage did not establish the current wage-shortfall measure it depends on. A result can only stand as high as its foundation. It's named here, not because it counts, but because pretending it doesn't exist would be its own kind of dishonesty.

That is enough to say the crisis left a measurable mark. It is not yet enough to say how that mark moved inside Greece year by year.

Put together with the rest of this piece, that leaves duration as a real part of the picture, not the whole of it: countries carrying more accumulated unemployment, more years of lost wages and more housing deterioration report more hardship even once today's conditions are accounted for, though that is an association across countries and not a demonstrated cause inside Greece. How much of the story that still leaves unaccounted for, and where this piece's evidence runs out, is what the next two sections settle.

What Remains Open

Up to this point, the evidence gives a fairly clear picture for most of the central questions. The wide gap between *reported hardship* and *income poverty* in Greece is tied closely to specific material deprivations. It also shows up in a country where the jobs recovery was not matched by an equivalent recovery in wages, material resources or purchasing power. There is also evidence that, in some areas, what matters is not only where a country stands today but how much weight it accumulated over the course of the crisis.

That picture, though, doesn't answer everything. Two questions get a more limited answer from the available data. First, the relationships found for accumulated burden show up clearly when comparing countries with each other. Showing whether the same relationship played out inside Greece, year by year, needs more annual observations and more within-country change than the data can currently offer: with roughly a decade of data, the relevant estimates stay too uncertain.

Second, while much of the extra hardship Greek households report can be explained statistically by deprivation measures, those measures come from the same survey as reported hardship itself, which makes the result less independent than it looks. There are also factors the available evidence simply doesn't yet cover well enough to give a clear picture.

Take them one at a time.

What Can We Say About Change Within the Country Itself?

The previous section showed that countries carrying more accumulated unemployment, wage non-recovery and housing pressure tend to report more hardship even once today's conditions are taken into account. That is a substantive finding, but it is mostly a statement about differences between countries.

A different question is whether the same relationship can be seen unfolding inside one country: whether hardship in Greece rose or fell as the crisis burden built up or eased. This project tested that version too, but roughly ten annual observations per country do not give enough precision for a clean answer.

Precise result. Across three related tests, no within-country estimate across the panel clearly supported the expected direction. The evidence therefore cannot show that hardship rose inside Greece as the damage accumulated.

Limits. These are three related checks on the same data, not three independent confirmations, and they weren't adjusted for running several checks at once.

FIGURE 9 The Strongest Evidence Comes From Between-Country Differences

Do we see the accumulated burden only when comparing countries, or also when tracking one country over time?

Accumulated measure	Between vs within				First difference (raw)	First difference p
	Between (SD)	Within (SD)	Between p	Within p		
Accumulated unemployment	0.5924	0.0296	0.0000	0.6867	0.0461	0.7324
Cumulative wage shortfall	0.6584	-0.0544	0.0130	0.3147	-0.0596	0.0284
Years wages below 2008	0.7271	0.0700	0.0025	0.0823	0.0721	0.4952
Cumulative GDP shortfall	0.3890	0.0674	0.0289	0.0600	0.0273	0.1442
Cumulative threshold shortfall	0.8271	0.0123	0.0000	0.5599	-0.0148	0.3917
Accumulated affordability pressure	-0.3953	-0.0764	0.3639	0.2825	-0.0298	0.0000
Compounded inflation since 2008	-0.1718	-0.1228	0.4947	0.3738	-0.0314	0.5766
Housing deterioration since 2010	0.9282	-0.0658	0.0000	0.2343	-0.0090	0.8679

[Figure 9](#) makes that distinction visible. Comparing countries against each other, the ones carrying more accumulated burden do tend to report more hardship. Trying to track the same relationship inside each country over time, the estimates become far less certain. So there is a fair amount known about how countries differ from one another, and less about how that specific mechanism played out inside Greece itself.

How Much Does the Explanation Depend on What Goes Into the Model?

The second open question concerns the *deprivation items* [from earlier](#), things like being unable to cover an unexpected expense, inadequate heating and payment arrears. These items track reported hardship very closely, and when added to the model alongside income poverty, they absorb most of Greece's excess.

That result matters, but it has one key catch: the deprivation items and reported hardship come from the same survey. That produces two equally defensible analytical choices. Including them draws on information very close to households' day-to-day economic experience. Excluding them avoids explaining one survey answer with other answers collected through the same instrument. Both versions were built, and Greece's position changes sharply depending on which one is used.

Precise result. Greece's residual reverses from positive to negative, and its rank from 3rd of 27 to 25th of 27, depending on whether the same-instrument deprivation predictor is included.

Limits. Neither specification is definitive; the two may not be merged or averaged, and selection between them may not be made on residual size.

FIGURE 10 One Predictor Flips Greece From Third-Worst to Twenty-Fifth

Does the answer depend on which model is chosen?

▼ Methods and limits

Read with this. NEITHER specification is definitive. They may not be merged or averaged, and selection may not be made on residual size.

Country	Reference specification	Deprivation-free companion	Change
Luxembourg	8.80	15.48	6.68
Cyprus	7.05	10.75	3.70
Greece	6.93	-9.39	-16.32
Latvia	6.32	4.65	-1.66

Romania	-10.32	9.76	20.08
Spain	-10.63	-10.06	0.57

[Figure 10](#) shows it: Greece moves from the third-worst country in Europe on *unexplained hardship* to the twenty-fifth, from a stark positive outlier to a stark negative one, on exactly the same rows of data, with one measure added or removed. The two results can't be averaged, and can't be chosen

between by which looks more plausible; doing that is exactly what would make a check like this meaningless. Which is why nothing later in this piece leans on it.

▼ The measures that went quiet, and the designs that failed

Not every present-day measure earned a place in the story so far, and the reason is statistical power rather than a verdict against them. Nine were tried; three worked. The other six mostly went quiet rather than failed outright: with twenty-seven countries and a decade of data, most of them could only have caught an effect bigger than any effect worth caring about. Silence isn't a verdict. A few can be set aside for real, at least at the size this design could catch, and they are all measures of price inflation. The rest simply weren't put under enough pressure to say either way.

Precise result. Six of nine current-level measures are inconclusive under the available statistical power, not unsupported. Annual food and housing inflation can be set aside with adequate power, and annual headline inflation at the magnitude this design could detect; compounded inflation since 2008 remains inconclusive.

Limits. Inconclusive is not evidence of absence; the exclusions that do hold are narrow and specific to the size this design could detect.

Two further ideas were meant to carry real weight here, and neither survived contact with the data. They are named rather than quietly dropped. A synthetic Greece, built to track the real one before 2008 and read the divergence after as the crisis effect, collapsed into a blend of essentially two countries and missed four of the six conditions it had been required to meet before anyone looked at the result. Its chart is not shown here, because a dramatic picture built on a counterfactual that thin would persuade readers of something the evidence can't actually support. And the sixteen-measure spread [from earlier](#) made Greece's position worse, not better, once it was asked to predict rather than just describe, and its direction flipped once other measures were held steady, left deliberately unexplained here, since inventing a story for a strange result in a design that already failed is how failed ideas come back from the dead. Both are recorded for what they are: attempts that didn't work, kept visible rather than erased.

Precise result. The synthetic-control comparison failed four of six pre-registered gates and is not usable; its own chart is withheld for that reason. Adding the sixteen-measure spread to the frozen model worsened Greece's residual and reversed its sign.

Limits. Both are attempts that did not work, not findings; the sign reversal in the second is deliberately left uninterpreted.

That is as far as the quantitative analysis goes. It has answered a substantial part of the original question, but not every possible mechanism behind Greece's particular pattern. Factors such as trust in institutions, adjustment policies, migration, taxation, health, and the way people answer subjective questions may also be part of the picture. Some of these are examined next with the available evidence; for others, all that can be done is describe what is known and what remains open.

This does not leave the earlier picture hanging. Instead, it leaves one last layer of questions: factors that may round out the picture but were not measured well enough, or cannot be tested the same way.

What the Numbers Still Miss

There is a simpler explanation for everything above, and it deserves to be taken seriously rather than waved away: maybe Greeks are just gloomier answerers. The evidence so far can't fully settle that: the strongest corroboration for *reported hardship*, the concrete deprivation items from earlier, comes from inside the same survey as the hardship question itself. The external evidence elsewhere in this piece — wages, employment, what households can actually buy, the *sixteen-measure spread* — doesn't share that problem, but none of it was built to test reporting style directly.

Financial Expectations and Life Satisfaction

A better test looks across different subjects entirely, drawing on a separate reporting-style comparison built for this project (`reporting_style_cross_indicator.csv`). A general tendency to answer darkly should drag everything down about equally; a pattern that is extreme on money and milder elsewhere points at circumstances instead. Read as descriptive corroboration rather than an independent test, the table below makes that comparison directly: Greece against the EU on three different kinds of question, not just the one this piece has leaned on so far.

MEASURE	GREECE	EU MEDIAN	GREECE'S POSITION
Reported hardship	66.7%	17.1%	1st of 27, worst first
Financial expectations	-43.2	-1.8	1st of 27, worst first
Life satisfaction	6.7	7.3	2nd of 28, worst first

Greece is worst in Europe on the two money questions and close to worst on general *life satisfaction*: a difference of degree, not of kind, which suggests some domain specificity, though a broader negative reporting tendency is not ruled out.

Greece is consistently among Europe's worst countries on life satisfaction and consistently worst on financial hardship and expectations. The greater extremity of the financial indicators suggests domain specificity, but does not rule out a broader negative reporting tendency.

The limits of this. Greece is second-WORST on life satisfaction by 2024, not middling; a broader negative reporting tendency is NOT ruled out; Greek life satisfaction ROSE over the observed period, 6.2 to 6.9; only its rank worsened, because other countries improved faster; the series begins in 2013, at the crisis trough, with no pre-crisis baseline.

One thing about that life-satisfaction number is worth holding onto, because it's easy to get backwards: it actually *rose* over the period. Describing Greece as merely ordinary or middling here would be wrong: it is second-worst in the EU by 2024. Its rank fell anyway, because other, faster-improving EU countries pulled further ahead, so reading that worsening rank as a falling level would be its own mistake. A falling rank is not the same thing as a falling number.

Pre-Crisis Wellbeing Baseline

One further check reaches back before the Eurostat series begins. A separate European survey shows Greece already sitting about 0.8 points below its comparison group before the crisis, falling further during it, and recovering its level, but not its relative position, by the 2020s. A long-standing pattern of lower reported wellbeing remains plausible on this evidence. It also cannot be established by it.

DESCRIPTIVE CORROBORATION

PRE-CRISIS WELLBEING BASELINE (ESS)

Across six rounds of a separate European survey, holding the same twelve countries fixed each time, Greece's level fell and then recovered while its position relative to the

others did not. This is descriptive corroboration and not a test.

What this lets us say. On a balanced set of 12 countries observed in every Greek ESS round, Greece already sat about 0.8 points below the median before the crisis, fell to 5.64 by 2010/11, and recovered its LEVEL to roughly the pre-crisis value by 2023/24. Its comparative position did not recover: the gap to the balanced median is wider than before the crisis, and Greece has been worst of the 12 since 2010/11. A longstanding low-wellbeing pattern therefore remains plausible and generic pessimism or reporting culture CANNOT be dismissed.

What it does not. Splicing ESS to the Eurostat EU-SILC series, or reading the two as one trajectory. Attaching any confidence interval, standard error or significance test to these means, which are approximate reconstructions from displayed weighted percentages. Comparing ALL-COUNTRY ranks across rounds, since the country set varies from 22 to 30. Treating the decade after 2010/11 as observed.

European Social Survey Data Portal, public Analysis tab for stflife (life satisfaction, 0-10), rounds 1, 2, 4, 5, 10 and 11. [source](#)

Health

Health is different from the factors that follow: it was tested, not skipped. Greece has one of the EU's highest rates of unmet medical need — worst in the Union by 2024, several times the typical member state — and that is a real, troubling fact about Greek life in its own right.

But four separate health measures, tested against the same baseline used elsewhere, do not explain the hardship gap: none of them clears the bar this project sets. Three of them — *self-rated health*, *long-standing illness* and *activity limitation* — carry a puzzling sign at the country level, where worse reported health goes with *less* reported hardship, and that flips once countries are compared with their own past rather than with each other: within a country, years of worse health are years of more hardship, the expected direction. The fourth, *unmet medical care*, doesn't have that problem — it points the expected way in both comparisons — but its result changes if any single country is dropped, which is why it doesn't clear the bar either. So the health fact stands as real, without becoming part of this piece's explanation for the gap.

Migration

Large numbers of working-age Greeks left during the crisis, and some have returned. This cuts both ways: plausibly a consequence of a broken labour market, and plausibly part of why the people who stayed look the way they do. Unlike most of the factors that follow, this one was tested directly, as an aggregate predictor of hardship across countries.

CONTEXTUAL CONSEQUENCE

MIGRATION

When migration was tested as an aggregate predictor of hardship across countries, no clear statistical relationship emerged.

What this lets us say. A plausible consequence of prolonged labour-market damage and a possible contributor to it. It is UNSUPPORTED as an independent aggregate predictor here.

What it does not. Reading it as a driver, or as ruled out. The aggregate migration test on this panel returned nothing ($p=0.4006$), which speaks to aggregate prediction and not to either causal direction.

Lazaretou, S. (2016), The Greek brain drain: the new pattern of Greek emigration during the recent crisis. Economic Bulletin, Bank of Greece, issue 43, pp. 31-53. [source](#)

Other factors often appear in accounts of the Greek crisis, and none of them was established here. Leaving them out silently would be misleading; treating them as findings would be worse, so they are recorded for what they are.

▼ Other possible factors

CONTEXTUAL EVIDENCE

INSTITUTIONAL TRUST

Trust in institutions is low in Greece, and there is a plausible route by which it could matter: a household that doesn't expect help to arrive may experience the same circumstances as more frightening. This piece has no check on that either way.

What this lets us say. May affect how households interpret insecurity; available evidence does not identify an independent effect.

What it does not. Presenting trust as an explanation of the residual, or implying it was tested and found to matter.

OECD (2024), OECD Survey on Drivers of Trust in Public Institutions - 2024 Results, Country Notes: Greece. OECD Publishing, Paris. [source](#)

LITERATURE-GROUNDED CONTEXT

CRISIS AND ADJUSTMENT POLICIES

The bailout programmes from 2010 reshaped incomes, job protections, pensions and public services at once and in a hurry. They are the backdrop to every accumulated measure described earlier.

What this lets us say. Help explain the historical setting; this project does not estimate their causal contribution.

What it does not. Attributing any share of the accumulated exposure to a specific programme or measure.

Andriopoulou, E., Kanavitsa, E. & Tsakloglou, P. (2020), Decomposing Poverty in Hard Times: Greece 2007-2016. LSE GreeSE Paper No. 149. [source](#)

FUTURE HYPOTHESIS

TAX BURDEN AND UNEQUAL TREATMENT

Published research establishes that Greece's system of indirect taxes became markedly harder on lower-income households across the crisis. If a household's position worsened through tax in a way income-based poverty measures capture badly, that would be one route to the kind of gap this report describes.

What this lets us say. Published incidence evidence establishes that Greece's indirect tax system became markedly more regressive over the crisis. Whether that channel contributes to the hardship gap is a plausible hypothesis and is NOT tested here.

What it does not. Any quantitative statement linking tax burden to the hardship gap. The literature is about incidence, not about this outcome, and this project tested nothing on tax.

Kaplanoglou, G. (2015), Who Pays Indirect Taxes in Greece? From EU Entry to the Fiscal Crisis. Public Finance Review 43(4), 529-556. [source](#)

CONTEXTUAL EVIDENCE

WEALTH CONCENTRATION SINCE 2019

Independent ECB data show that of the €224.8bn increase in Greek household net wealth between 2019 and early 2026, about 72.6% went to the wealthiest fifth of households, while the bottom half accounted for about 9.2% and saw its own share of total wealth slip slightly. A national wealth total climbing while most of the gain bypasses the bottom half of the distribution is one plausible way that

recovery and persistent hardship can sit side by side — this project never tested wealth against its own hardship measure directly, so it is offered as a plausible mechanism, not a demonstrated one.

What this lets us say. Independent ECB distributional wealth accounts show that of the €224.8bn increase in Greek household net wealth between mid-2019 and early 2026 (+32.2%), about 72.6% accrued to the wealthiest fifth of households while the bottom half accounted for about 9.2%; the bottom half's own share of total wealth slipped slightly, from roughly 9.5% to 9.4%. This offers one plausible mechanism for how aggregate recovery and persistent reported hardship can coexist: a rising net-wealth total does not evenly reach the households reporting the most difficulty.

What it does not. Treating this as tested against this project's reported-hardship findings, or as an established explanation for the 52.6-point gap: it sits partly outside the 2015-2024 window and was never checked against any model here. Reading a rising net-wealth figure as equivalent to rising disposable income or an improved ability to pay bills: these changes are driven mostly by property and financial-asset valuations, not household cash flow. Treating the ECB's distributional wealth accounts as final: the ECB itself labels them experimental, combining household survey data with quarterly national accounts and extrapolating between survey waves.

What It Adds Up To

Greek households report struggling at a rate far above what the official poverty figure predicts, and have done so consistently for a decade. What runs through the whole of this piece is that no single official number captures what Greek households are reporting: each one misses something different, and the measure that catches what the others miss is not the headline figure. Part of that distance is now easier to understand.

AROP measures something narrower than the economic experience it is often asked to summarise. Because the poverty line moves with national income, it can stay relatively stable even as living standards fall substantially. *AROPE* widens the picture, but covers only part of the gap. Reported hardship, meanwhile, moves with specific material deprivations, and conditions in work, material resources and purchasing power add information *AROP* alone does not capture. There is also evidence that, in some areas, what matters is not only today's conditions but the weight accumulated over the course of the crisis.

What recovered was narrower than the word “recovery” suggests. Employment improved substantially, and housing pressure eased. But GDP per person never returned to its 2008 level, real wages remained far below it, and purchasing power fell further behind the European median. The checks that could be run did not reduce reported hardship to pessimism or measurement error. It moves with concrete material difficulties and appears across a much wider range of indicators.

The 52.6-point gap remains largely unexplained. That does not make it any less real. It means that none of the independently measured mechanisms tested here can, robustly and on its own, account for its size. The official poverty rate is not wrong: it measures who falls below a threshold set relative to today’s national median income. But on its own, it cannot tell us whether Greek households have regained the economic security they had before the crisis. Perhaps, then, the problem is not that Greek households failed to recognize the recovery. It is that the public story treated the recovery as complete before it had fully reached them. This closing synthesis is author interpretation rather than a new empirical result: it follows directly from what the analysis showed AROP alone misses, not from an additional test that itself produced this finding.
